

2D Interactive Drawing Process Work

Problems & Solutions

- Problem: Objects coded to follow the location of the mouse naturally start from the mouse's location and draw to the right and down. My desired effect is for the objects to be centered on the mouse.
 - Solution: When assigning `Input.GetMouseX` and `Y`, subtraction is available to alter where the objects are drawn on the grid. Subtracting the x and y values allows the objects to be centered on the mouse while still following mouse movement.
- Problem: Initial design concepts too time-consuming and detailed compared to the available grid space. Concept art doesn't translate well into the final game.
 - Solution: Change the designs to better fit the time constraints and skill level of the programmer involved (me). A specific example is the sheep joke. Instead of overly complicated smaller sheep piloting a robot mech, the sheep is instead comically skinny beneath its wool. Easier to draw, retains intended humor of the reveal.
- Problem: Do not know how to map a reaction to an area more specific than a rectangle.
 - Could not find a solution.

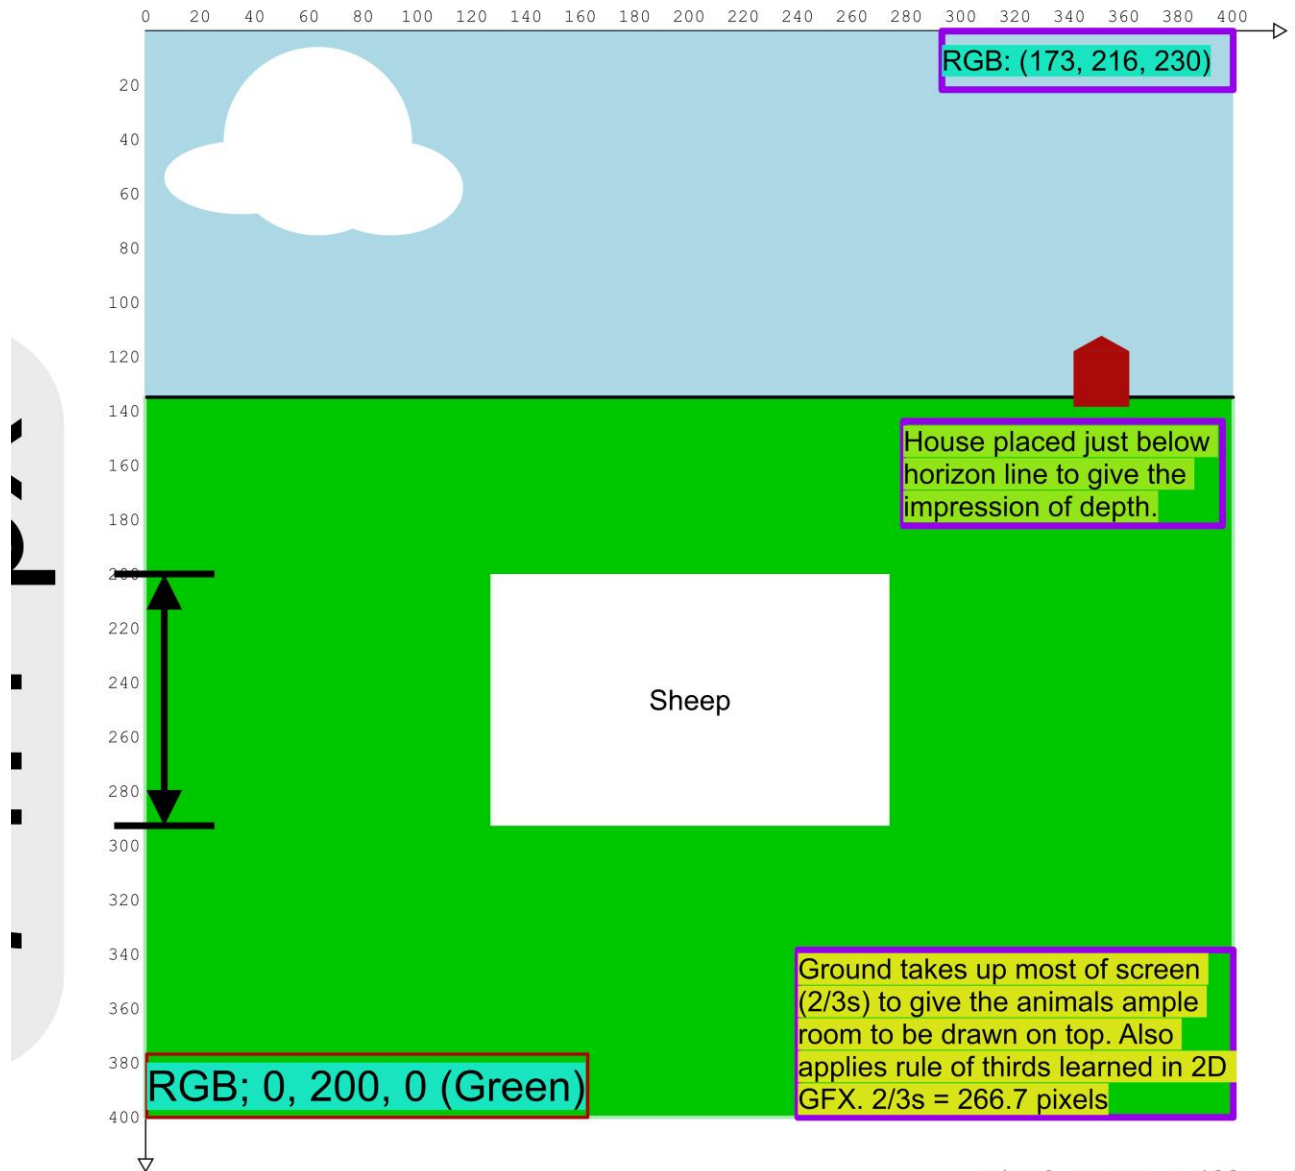

Notes

- Feature Scrapped: Most animals removed to not take too much time intricately drawing and placing both animals and skeletons. The final design includes one land animal to showcase features.
- Using Affinity to create digital notes and mockups for final design.
